“I am the master of my fate, I am the captain of my soul”

from Invictus, by William Ernest Henley
Software testing can never guarantee that sorting algorithms respond correctly to all kinds of inputs. Instead, formal proofs can be used to assert that an algorithm is consistently correct. Manual formalization might become prone to human error due to a large number of proof steps. Hence, the need for a proof assistant is crucial, which is a software-based tool designed to help with the development of formal proofs in an iterative and automated fashion. By employing Isabelle/HOL, which is one of the major proof assistants, I formalized some sorting algorithms by checking the multiplicity, and that the output is sorted. These algorithms are: tail and non-tail recursive insertion and selection sort, and also tail recursive merge sort. Moreover, I used Isabelle’s Isar language to present readable formal proofs as opposed to other formalizations of sorting algorithms in Isabelle/HOL.
Here one can also find the code for the formalization of sorting algorithms in Isabelle/HOL:

Introduction

1.1 Sorting

An algorithm receives a value or a set of values, also called input, and then follows a set of rules to produce some value, also called output. In particular, sorting algorithms aim to solve the sorting problem by rearranging the records of a collection in a defined order. The sorting problem can be formally defined as follows [2]:

**Input:** A sequence of n numbers \(<r_1, r_2, ..., r_n>\)

**Output:** A permutation (rearrangement) \(<r'_1, r'_2, ..., r'_n>\) of input sequence such that \(r'_1 \leq r'_2 \leq ... \leq r'_n\)

The above formal description shows two main characteristics for the output. The first characteristic is that the output is a permutation of the input. The other characteristic is that the output is in increasing order: this means that any element that belongs to the output is always smaller than or equal to its successor. Next, two examples showing a correct and a wrong output after sorting is found:

**Correct output:** Input: \([4, 3, 2, 1, 0]\) and Output: \([0, 1, 2, 3, 4]\)

**Wrong output:** Input: \([4, 4, 3, 2, 1, 0, 0]\) and Output: \([0, 1, 2, 3, 4]\)

On the one hand, the correct output is clearly sorted because (1) the output sequence \(0 \leq 1 \leq 2 \leq 3 \leq 4\) holds, and (2) it is a rearrangement of the input. On the other hand, the wrong output is in increasing order. However; it is not a permutation of the input since the output does not include the duplicates of the numbers 4 and 0.
1. INTRODUCTION

1.2 Orders

The binary relation ≤ used for sorting elements is required to be a total order. This binary relation meets the requirements for a partial order and an extra condition known as the comparability condition. A formal definition for the partial order relation follows [3]:

A partial order on a set S is a binary relation R such that:

• \( \forall a \in S : (a, a) \in R \) (R is reflexive)
• \( \forall a, b, c \in S : (a, b) \in R \land (b, c) \in R \rightarrow (b, c) \in R \) (R is transitive)
• \( \forall a, b, c \in S : (a, b) \in R \land (b, c) \in R \rightarrow a = b \) (R is antisymmetric)

Let R be a partial order relation on Set S. Any two elements \( y, x \in S \) are comparable if either \( xRy \) or \( yRx \). For example, either \( x \leq y \) or \( y \leq x \). When the previous condition holds, then the relation R is comparable.

1.3 Pure functional programming

Pure functional programming is a programming paradigm where the functions do not have side effects, and the input is not modified. In other words, the functions do not utilize variables but constants. Moreover, the functions cannot access any other data than the one contained in its own arguments or inputs [4].

```isabelle
primrec remove1 :: "'a ⇒ 'a list ⇒ 'a list" where
"remove1 x [] = []" |
"remove1 x (y # xs) = (if x = y then xs else y # remove1 x xs)"
```

**Figure 1.1:** remove1: a predefined Isabelle/HOL function

Isabelle/HOL reassembles a purely functional programming language. Therefore, it includes base types, type constructors, function types, and type variables. It also has terms that can be formed by applying functions to arguments [5]. Figure 1.1 shows the built-in function `remove1`, which receives as input an element \( x \) and a list of type \( a \), then removes \( x \) at most one time from the list. Finally, it outputs the result in a list of type \( a \).

Purely functional programming code is similar to a recursively defined mathematical function, this can be seen in figure 1.1 and 1.2. To illustrate, the first constructor in function `remove1`, figure 1.1, is similar to equation 1.1 in figure 1.2 and this is also the case for the other constructor and equation.
1.4 Structural induction

Structural induction is a mathematical proof technique which is similar to mathematical induction, but the latter can only work on the domain of $\mathbb{N}$, whereas the former can only work on recursively defined data types [6]. For example, lists and trees. Besides, we can state that structural induction accepts $\mathbb{N}$ since these numbers can be defined as a recursive data type. Next, a concrete example of structural induction will be shown by proving a particular property of the recursively defined function $\text{remove1}$ in figure 1.2:

**Lemma 1.4.1** Removing an element $y \in \text{set}(x\#xs)$ from list $x\#xs$ always yields to a strictly smaller list than the original list. Formally:

$$\forall y, x, xs (y \in \text{set}(x\#xs) \rightarrow \text{length}(\text{remove1}(y, (x\#xs))) < \text{length}(x\#xs))$$

**Proof** The proof is by structural induction on list $xs$.

**Base case:** when $xs = []$, then show $\text{length}(\text{remove1}(y, [x])) < \text{length}([x])$ holds by assuming that $y \in \text{set}([x])$

$$\text{length}(\text{remove1}(y, (x\#[]))) = \text{length}(\text{remove1}(x, (x\#[]))) = \text{length}([]) < \text{length}([x])$$

**Induction hypothesis:**

$$\forall y, x, xs (y \in \text{set}(x\#xs) \rightarrow \text{length}(\text{remove1}(y, (x\#xs))) < \text{length}(x\#xs))$$

**Inductive step:** assuming that IH holds, then show:

$$\forall y, a, x, xs (y \in \text{set}(a\#x\#xs) \rightarrow \text{length}(\text{remove1}(y, (a\#x\#xs))) < \text{length}(a\#x\#xs))$$

Fix: $y, a, x, xs$
Assume: $y \in \text{set}(a\#x\#xs)$
1. INTRODUCTION

Case 1 \( y = a \).

\[
\text{length}(\text{remove1}(y, (a\#x\#xs))) = \text{length}(\text{remove1}(a, (a\#x\#xs))) = \text{length}(x\#xs) < \text{length}(a\#x\#xs)
\]

[By \( y=a \)]

Case 2 \( y \in \text{set}(x\#xs) \).

\[
\text{length}(\text{remove1}(y, (a\#x\#xs))) = \text{length}(a\#\text{remove1}(y, (x\#xs))) = \text{length}([a]) + \text{length}(\text{remove1}(y, (x\#xs))) < \text{length}([a]) + \text{length}(x\#xs) = \text{length}(a\#x\#xs)
\]

[By using \([H] \) and since \( y \in \text{set}(x\#xs) \)]

\[
\therefore \text{By the principle of structural induction, the lemma 1.4.1 holds.}
\]

Q. E. D.

1.5 Computational induction

\[
\text{fun splice :: } 'a\ \text{list} \Rightarrow 'a\ \text{list} \Rightarrow 'a\ \text{list} \text{ where }\\
\ "\text{splice } [] \ ys = ys" | \\
\ "\text{splice } xs \ [] = xs" | \\
\ "\text{splice } (x\#xs) \ (y\#ys) = x\#y\#\text{splice } xs \ ys"
\]

\textbf{Figure 1.3:} splice: a predefined Isabelle/HOL function

This kind of induction follows the recursive pattern in a function to form an induction principle which can be used to simplify inductive proofs, \textit{Concrete semantics, page 18} [7].

For example, the induction principle of any property \( P \ zs \) for the splice function in figure [1.3] follows:

\[
\forall ys. P [] ys \land x, xs. P (x\#xs) [] \land x, y, xs, ys. P \ xs \ ys \implies P (x\#xs) (y\#ys)
\]

1.6 Isabelle/HOL

Isabelle/HOL is a specialization of the generic proof assistant Isabelle for higher-order logic (HOL). Proofs are carried out by using the Isar language, which allows presenting
proofs in a human-readable fashion \[8\]. Isabelle/HOL also includes productivity tools such as Sledgehammer, which invokes multiple automatic theorem provers to try to solve a particular problem. Figure 1.4 shows a fragment of a proof in Isabelle/HOL. The entire proof is located in Appendix IV.

Isabelle/HOL can form a chain of intermediate results, also known as proof by calculational reasoning, that are composed by basic principles, such as transitivity of $\leq$, $<$ or $=.$ Calculations are formed by using the commands also and finally, and the "..." notation, which holds the value of the most recent right-hand-side expression \[9\]. This proof pattern is found in figure 1.4 line 5-10.

In figure 1.4 line 2, structural induction is carried out on list $xs$ for any $y$ and $x$. At this stage, Isabelle/HOL shows two subgoals to prove:

1. $\forall y \; x \; . \; y \in \text{set} \; [x] \implies \text{length} \; (\text{remove1} \; y \; [x]) < \text{length} \; [x]$

2. $\forall a \; xs \; y \; x . \ (\forall y \; x \; . \; y \in \text{set} \; (x#xs) \implies \text{length} \; (\text{remove1} \; y \; (x#xs)) < \text{length} \; (x#xs)) \implies y \in \text{set} \; (x#a#xs) \implies \text{length} \; (\text{remove1} \; y \; (x#a#xs)) < \text{length} \; (x#a#xs)$

The first subgoal refers to the base case and the second to the inductive step, which specifies two premises and a conclusion. Figure 1.4 does not show the resolution for the base case; however, line 4-8 shows a resolution for case True, which represents the case $y \in \text{set}(a#xs)$. This resolution is almost identical to the chain of (in)equations presented in Case 2, inductive step, previous section, the only difference is that case True uses $a$ instead of $x$.

```isabelle
lemma "y \in \text{set} \; (x#xs) \implies \text{length} \; (\text{remove1} \; y \; (x#xs)) < \text{length} \; (x#xs)"
proof (induct xs arbitrary: y x)
  ... 
  case True
  have "length \; (remove1 \; y \; (x#a#xs)) = length \; (x#remove1 \; y \; (a#xs))" ...
  also have "... = length [x] + length \; (\text{remove1} \; y \; (a#xs))" ...
  also have "... < length \; [x] + length \; (a#xs)" ...
  also have "... = length \; (x#a#xs)" ...
  finally show "length \; (\text{remove1} \; y \; (x#a#xs)) < length \; (x#a#xs)" by this
next
  case False
  ... 
qed
```

Figure 1.4: Proving lemma 1.4.1 using Isabelle/HOL
1. INTRODUCTION
Informal proofs for sorting

2.1 Predefined functions and data types, and derived lemmas

Table 2.1 lists all the Isabelle/HOL functions used to implement and prove the sorting algorithms. Keep in mind that the notation for multisets in Isabelle/HOL is \{#...#\}. For example, a multiset of natural number is defined as \{#1, 2, 3#\}.

<table>
<thead>
<tr>
<th>Function</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Min :: 'a set ⇒ 'a</td>
<td>returns the smallest element from a set.</td>
</tr>
<tr>
<td>Max :: 'a set ⇒ 'a</td>
<td>returns the largest element from a set.</td>
</tr>
<tr>
<td>remove1 :: 'a ⇒ 'a list ⇒ 'a list</td>
<td>removes at most one element from a list.</td>
</tr>
<tr>
<td>sorted :: 'a list ⇒ bool</td>
<td>checks whether a list is in total order.</td>
</tr>
<tr>
<td>length :: 'a list ⇒ nat</td>
<td>returns the number of elements in a list.</td>
</tr>
<tr>
<td>mset :: 'a list ⇒ 'a multiset</td>
<td>transforms a list into a multiset.</td>
</tr>
<tr>
<td>+ :: 'a multiset ⇒ 'a multiset ⇒ 'a multiset</td>
<td>multiset union.</td>
</tr>
<tr>
<td>set :: 'a list ⇒ 'a set</td>
<td>transforms a list into a set.</td>
</tr>
<tr>
<td>take :: nat ⇒ 'a list ⇒ 'a list</td>
<td>takes the n first elements of a list.</td>
</tr>
<tr>
<td>drop :: nat ⇒ 'a list ⇒ 'a list</td>
<td>drops the n first elements of a list.</td>
</tr>
</tbody>
</table>

Predefined functions such as take and drop come with predefined lemmas. The automatic theorem provers, such as Sledgehammer, can prove variations of these predefined lemmas. The following lemmas are modifications of predefined lemmas that Isabelle/HOL can automatically prove.
2. INFORMAL PROOFS FOR SORTING

Lemma 2.1.1 (take drop permutation)
\[ \forall n, xs (\text{mset} (\text{take}(n, xs)) + \text{mset} (\text{drop}(n, xs)) = \text{mset}(xs)) \]

Lemma 2.1.2 (rest permutation)
\[ \forall y, ys (\text{mset} (\text{remove}1(\text{Min}(\text{set}(y\#ys)), (y\#ys))) = \text{mset}(y\#ys) - \{\#\text{Min}(\text{set}(y\#ys))\#\}) \]

2.2 Merge and insertion sort

Proving an implementation of insertion sort will lead more or less directly to show merge sort. However, only merge sort is presented in this section to prevent from making chapter 2 too long. Nevertheless, for the sake of completeness, the informal proofs for insertion sort are available in appendix I. If one encounters challenging to follow the informal proofs for merge sort, then one should first fully understand the informal proofs for insertion sort, which are based entirely on structural induction. I used as inspiration for the insertion sort correctness the slides of the Computer Science Theory course, University of Minnesota Duluth, page 9 [10].

\[
\begin{align*}
\text{merge}(xs, []) &= xs \\
\text{merge}([], ys) &= ys \\
\text{merge}(x\#xs, y\#ys) &=
\begin{cases}
  x\#\text{merge}(xs, y\#ys), & \text{if } x \leq y \\
  y\#\text{merge}(x\#xs, ys), & \text{otherwise}
\end{cases}
\end{align*}
\]

**Figure 2.1:** merge: a recursively defined mathematical function

\[
\begin{align*}
\text{merge}\_\text{sort}([]) &= [] \\
\text{merge}\_\text{sort}([x]) &= [x] \\
\text{merge}\_\text{sort}(xs) &= \text{merge}(\text{merge}\_\text{sort}(\text{left}), \text{merge}\_\text{sort}(\text{right})) \\
& \quad \text{where half} = (\text{length}(xs) \div 2) \\
& \quad , \text{left} = \text{take}(\text{half}, xs) \\
& \quad \text{and right} = \text{drop}(\text{half}, xs)
\end{align*}
\]

**Figure 2.2:** merge\_\text{sort}: a recursively defined mathematical function

Lemma 2.2.1 (merge order) The merge function yields a sorted list (output) if the input list xs and ys are sorted. Formally:
\[ \forall xs, ys (\text{sorted}(xs) \land \text{sorted}(ys) \rightarrow \text{sorted}(\text{merge}(xs, ys))) \]
2.2 Merge and insertion sort

Proof The proof is by computational induction on list \(xs\) and \(ys\).

**Base case 1 and 2:** In the base case 1, the list \(ys\) is empty, and in the base case 2, the list \(xs\) is empty. Then it follows that base case 1 and 2 output, lists \(xs\) and \(ys\), respectively. Therefore, both cases hold, because we assume that \(ys\) and \(xs\) are sorted.

**Induction hypotheses:**

IH.1: \(\forall y,xs,ys (\text{sorted}(xs) \land \text{sorted}(y\#ys) \rightarrow \text{sorted}(\text{merge}(xs, y\#ys)))\)

IH.2: \(\forall x,xs,ys (\text{sorted}(x\#xs) \land \text{sorted}(ys) \rightarrow \text{sorted}(\text{merge}(x\#xs, ys)))\)

**Inductive step:** assuming that both, IH.1 and IH.2 hold, then show:

\(\forall x,y,xs,ys (\text{sorted}(x\#xs) \land \text{sorted}(y\#ys) \rightarrow \text{sorted}(\text{merge}(x\#xs, y\#ys)))\)

Fix: \(x, y, xs, ys\)
Assume: \(\text{sorted}(x\#xs) \land \text{sorted}(y\#ys)\)

Case 1 \(x \leq y\). The premise \(\text{sorted}(x\#xs)\) implies \(\text{sorted}(xs)\), because removing the first element of a sorted list leaves the rest of the list sorted. \(\text{sorted}(xs) \land \text{sorted}(y\#ys)\) holds, then from IH.1, it follows that \(\text{sorted}(\text{merge}(xs, y\#ys))\) holds too. Moreover, by definition of merge function \(\text{merge}(x\#xs, y\#ys) = x\#\text{merge}(xs, (y\#ys))\). Hence, the expression \(\text{sorted}(x\#\text{merge}(xs, (y\#ys)))\) holds, because \(\text{merge}(xs, y\#ys), y\#ys\) and \(x\#xs\) are sorted, and \(x \leq y\).

Case 2 \(x > y\). Similar to case 1, \(\text{sorted}(x\#xs) \land \text{sorted}(ys)\) holds, then from IH.2, it follows that \(\text{sorted}(\text{merge}(x\#xs, ys))\) holds too. Moreover, by definition of merge function \(\text{merge}(x\#xs, y\#ys) = y\#\text{merge}(x\#xs, ys)\). Hence, \(\text{sorted}(y\#\text{merge}(x\#xs, ys))\) holds, because \(\text{merge}(x\#xs, ys), y\#ys\) and \(x\#xs\) are sorted, and \(x > y\).

\(\therefore\) By the principle of computational induction, the lemma \[2.2.1\] holds. Q. E. D.

**Lemma 2.2.2 (merge permutation)** The merge function output is a permutation of its input. Formally:

\(\forall xs,ys (\text{mset}(\text{merge}(xs, ys)) = \text{mset}(xs) + \text{mset}(ys))\)

Proof The proof is by computational induction on list \(xs\) and \(ys\).

**Base case 1:** when \(xs = []\), then show \(\text{mset}(\text{merge}([], ys)) = \text{mset}([]) + \text{mset}(ys)\) holds.

\[
\begin{align*}
\text{mset}(\text{merge}([], ys)) \\
= \text{mset}(ys) & \quad \text{[By definition of function merge]} \\
= \text{mset}([]) + \text{mset}(ys)
\end{align*}
\]
2. INFORMAL PROOFS FOR SORTING

**Base case 2:** when \( y_s = [] \), then show \( \text{mset}(\text{merge}(x_s, [])) = \text{mset}(x_s) + \text{mset}([]) \) holds.

\[
\text{mset}(\text{merge}(x_s, [])) \\
= \text{mset}(x_s) \\
= \text{mset}(x_s) + \text{mset}([])
\]

**Induction hypotheses:**

IH.1: \( \forall y, x_s, y_s \ (\text{mset}(\text{merge}(x_s, y\#y_s)) = \text{mset}(x_s) + \text{mset}(y\#y_s)) \)

IH.2: \( \forall x, x_s, y_s \ (\text{mset}(\text{merge}(x\#x_s, y_s)) = \text{mset}(x\#x_s) + \text{mset}(y_s)) \)

**Inductive step:** assuming that, both, IH.1 and IH.2 holds, then show:

\( \forall x, y, x_s, y_s \ (\text{mset}(\text{merge}(x\#x_s, y\#y_s)) = \text{mset}(x\#x_s) + \text{mset}(y\#y_s)) \)

Fix: \( x, y, x_s, y_s \)

**Case 1** \( x \leq y \).

\[
\text{mset}(\text{merge}(x\#x_s, y\#y_s)) \\
= \text{mset}(x\#\text{merge}(x_s, y\#y_s)) \\
= \{\#x\} + \text{mset}(\text{merge}(x_s, y\#y_s)) \\
= \{\#x\} + \text{mset}(x_s) + \text{mset}(y\#y_s) \\
= \text{mset}(x\#x_s) + \text{mset}(y\#y_s)
\]

**Case 2** \( x > y \).

\[
\text{mset}(\text{merge}(x\#x_s, y\#y_s)) \\
= \text{mset}(y\#\text{merge}(x\#x_s, y_s)) \\
= \{\#y\} + \text{mset}(\text{merge}(x\#x_s, y_s)) \\
= \{\#y\} + \text{mset}(x\#x_s) + \text{mset}(y_s) \\
= \text{mset}(x\#x_s) + \text{mset}(y\#y_s)
\]

\( \therefore \) By the principle of computational induction, the lemma 2.2.1 holds. Q. E. D.

**Theorem 2.2.1 (merge_sort order)** The merge_sort function yields a sorted list (output). Formally:

\( \forall x_s(\text{sorted}(\text{merge_sort}(x_s))) \)

**Proof** The proof is by computational induction on list \( x_s \).
2.2 Merge and insertion sort

**Base case 1 and 2:** The base case 1 is the empty list, and the base case 2 is \([x]\). Therefore, both cases hold since the empty list and \([x]\) are always sorted.

**Induction hypotheses:** Let \(l\) be \(\forall x, xs (\text{take}((\text{length}(x#xs) \text{ div } 2), (x#xs)))\) and \(r\) be \(\forall x, xs (\text{drop}((\text{length}(x#xs) \text{ div } 2), (x#xs)))\).

IH.1: \(\forall l (\text{sorted} (\text{merge} _\text{sort} (l)))\)

IH.2: \(\forall r (\text{sorted} (\text{merge} _\text{sort} (r)))\)

**Inductive step:** assuming that, both, IH.1 and IH.2 hold, then show:

\(\forall x, xs (\text{merge} _\text{sort} (x#xs))\)

Fix: \(x, xs\)
Let \(\text{half}\) be \(\text{length}(x#xs) \text{ div } 2\), \(\text{left}\) be \(\text{take} (\text{half}, x#xs)\) and \(\text{right}\) be \(\text{drop} (\text{half}, x#xs)\).

By IH.1 and IH.2 \(\text{merge} _\text{sort} (\text{left})\) and \(\text{merge} _\text{sort} (\text{right})\) are sorted. Moreover, by definition of merge_sort \(\text{merge} _\text{sort} (x#xs) = \text{merge} (\text{merge} _\text{sort} (\text{left}), \text{merge} _\text{sort} (\text{right}))\).

Hence, \(\text{sorted} (\text{merge}(\text{merge} _\text{sort} (\text{left}), \text{merge} _\text{sort} (\text{right})))\) holds, because lemma 2.2.1 shows that if the merge function receives as input two sorted lists, then the merge function produces a sorted list.

\(\therefore\) By the principle of computational induction, the theorem 2.2.1 holds. Q. E. D.

**Theorem 2.2.2 (merge_sort permutation)** The merge_sort function output is a permutation of its input. Formally:

\(\forall xs (\text{mset}(\text{merge} _\text{sort} (xs)) = \text{mset}(xs))\)

**Proof** The proof is by computational induction on list \(xs\).

**Base case 1 and 2:** The base case 1 is the empty list, and the base case 2 is \([x]\). By definition of merge_sort, base case 1 and 2 output the empty list and \([x]\), respectively. Therefore, both cases hold since both input and output are the same.

**Induction hypotheses:** Let \(l\) be \(\forall x, xs (\text{take}((\text{length}(x#xs) \text{ div } 2), (x#xs)))\) and \(r\) be \(\forall x, xs (\text{drop}((\text{length}(x#xs) \text{ div } 2), (x#xs)))\).

IH.1: \(\forall l (\text{mset} (\text{merge} _\text{sort} (l)) = \text{mset}(l))\)

IH.2: \(\forall r (\text{mset} (\text{merge} _\text{sort} (r)) = \text{mset}(r))\)
2. INFORMAL PROOFS FOR SORTING

**Inductive step:** assuming that, both, IH.1 and IH.2 hold, then show:

\[ \forall x, xs (mset(merge\_sort(x#xs)) = mset(x#xs)) \]

Fix: x, xs

Let half be length(x#xs) div 2, left be take(half, x#xs) and right be drop(half, x#xs).

\[
\begin{align*}
mset(merge\_sort(x#xs)) &= mset(merge(merge\_sort(left), merge\_sort(right))) & \text{[By merge\_sort definition]} \\
&= mset(merge\_sort(left)) + mset(merge\_sort(right)) & \text{[By using lemma 2.2.2]} \\
&= mset(left) + mset(right) & \text{[By using IH.1 and IH.2]} \\
&= mset(x#xs) & \text{[By using lemma 2.1.1]}
\end{align*}
\]

∴ By the principle of computational induction, the theorem 2.2.2 holds. Q. E. D.

2.3 Selection sort

\[
\begin{align*}
selection\_sort([]) &= [] & (2.1) \\
selection\_sort(x#xs) &= \text{minimum}\#selection\_sort(rest) & (2.2) \\
\text{where } \text{minimum} &= \text{Min}(\text{set}(x#xs)) & (2.3) \\
\text{and } \text{rest} &= \text{remove1}(\text{minimum}, (x#xs)) & (2.4)
\end{align*}
\]

Figure 2.3: selection\_sort: a recursively defined mathematical function

**Lemma 2.3.1 (selection\_sort halts)** *For any given list, selection\_sort function always terminates.*

**Proof** Termination proof for the selection\_sort recursive case is not trivial, because the recursive calls use as input the rest of the list x#xs, figure 2.3. The halting of the recursive case can be shown by comparing the length of list x#xs, left-hand side, and the length of the rest of the list, ride-hand side:

\[ \text{length(rest)} < \text{length(x#xs)} \]

∴ By the lemma 1.4.1 remove member, the lemma 2.3.1 holds, because the rest is smaller than list x#xs since removing one member of any list, with at least one element, always reduce the length of the original list. Q. E. D.
2.3 Selection sort

**Theorem 2.3.1 (selection_sort permutation)** The selection_sort function output is a permutation of its input. Formally:

$$\forall xs (\text{mset}(\text{selection_sort}(ys)) = \text{mset}(ys))$$

**Proof** The proof is by computational induction on list $ys$.

**Base case:** We have $\text{mset}(\text{selection_sort}([]))$ since $ys = []$. Moreover, we can rewrite this expression to $\text{mset}([])$ by using the selection_sort definition. Therefore, the base case holds, because from $\text{mset}(\text{selection_sort}([]))$ we can get $\text{mset}([])$.

**Induction hypothesis:** Let $re$ be $\forall y, ys (\text{remove1}(\text{Min}(\text{set}(y#ys)), (y#ys)))$.

$$\forall re (\text{mset}(\text{selection_sort}(re)) = \text{mset}(re))$$

**Inductive step:** assuming that IH holds, then show:

$$\forall y, ys (\text{mset}(\text{selection_sort}(y#ys)) = \text{mset}(y#ys))$$

Fix: $y, ys$
Let $\text{minimum}$ be $\text{Min} (\text{set}(y#ys))$ and let $\text{rest}$ be $\text{remove1}(\text{minimum}, (y#ys))$.

**Case 1** $\text{minimum} = y$.

$$\text{mset}(\text{selection_sort}(y#ys))$$
$$= \text{mset}(\text{minimum}#\text{selection_sort}(\text{rest}))$$
$$= \{\#\text{minimum}\#\} + \text{mset}(\text{selection_sort}(\text{rest}))$$
$$= \{\#\text{minimum}\#\} + \text{mset}(\text{rest})$$
$$= \{\#\text{minimum}\#\} + \text{mset}(\text{remove1}(y,y#ys))$$
$$= \{\#y\#\} + \text{mset}(ys)$$
$$= \text{mset}(y#ys)$$

**Case 2** $\text{minimum} \neq y$.

$$\text{mset}(\text{selection_sort}(y#ys))$$
$$= \text{mset}(\text{minimum}#\text{selection_sort}(\text{rest}))$$
$$= \{\#\text{minimum}\#\} + \text{mset}(\text{selection_sort}(\text{rest}))$$
$$= \{\#\text{minimum}\#\} + \text{mset}(\text{rest})$$
$$= \{\#\text{minimum}\#\} + (\text{mset}(y#ys) - \{\#\text{minimum}\#\})$$
$$= \text{mset}(y#ys)$$
2. INFORMAL PROOFS FOR SORTING

∴ By the principle of computational induction, the theorem 2.3.1 holds. Q. E. D.

Theorem 2.3.2 (selection_sort order) The selection_sort function yields a sorted list (output). Formally:

$$\forall xs \text{sorted}(\text{selection_sort}(xs))$$

**Proof** The proof is by computational induction on list \(xs\).

**Base case:** We have \(mset(\text{sorted_sort}([]))\) since \(xs = []\). Moreover, we can rewrite this expression to \(\text{sorted}([])\) by using the selection_sort definition. Therefore, the base case holds, because the empty list is always sorted.

**Induction hypothesis:** Let \(re\) be \(\forall x, xs(\text{remove1}(\text{Min}(\text{set}(x\#xs)), (x\#xs))).\)

$$\forall re \text{sorted}(\text{selection_sort}(re))$$

**Inductive step:** assuming that IH holds, then show:

$$\forall x, xs \text{sorted}(\text{selection_sort}(x\#xs))$$

**Fix:** \(x, xs\)

Let \(\text{minimum}\) be \(\text{Min}(\text{set}(x\#xs))\) and let \(\text{rest}\) be \(\text{remove1}(\text{minimum}, (x\#xs)).\)

1. Claim 1: \(mset(\text{selection_sort}(\text{rest})) = mset(x\#xs) - \{\#\text{minimum}\#\}\)

   **Proof (Subproof)**
   
   \[
   \begin{align*}
   mset(\text{selection_sort}(\text{rest})) \\
   = mset(\text{rest}) & \quad \text{[By using theorem 2.3.1]} \\
   = mset(x\#xs) - \{\#\text{minimum}\#\} & \quad \text{[By using lemma 2.1.2]} \\
   \end{align*}
   \]

   ∴ Claim 1 holds. Q. E. D.

2. Claim 2: \(\forall n (n \in \text{set}(\text{selection_sort}(\text{rest})) \land \text{minimum} \leq n)\) holds by using Claim 1.

By IH the expression \(\text{selection_sort}(\text{rest})\) is sorted, but it also has to be a permutation of the original list \(x\#xs\) without the minimum, otherwise, \(\text{selection_sort}(\text{rest})\) might include some number \(n\) such that \(\exists n (n \leq \text{minimum} \land n \in \text{set}(\text{selection_sort(\text{rest}))})\) holds. Claim 1 shows that indeed the \(\text{selection_sort}(\text{rest})\) is a permutation. Moreover, by \(\text{selection_sort}\) definition \(\text{selection_sort}(x\#xs) = \text{minimum}\#\text{selection_sort}(\text{rest})\). Hence, \(\text{sorted}(\text{minimum}\#\text{selection_sort}(\text{rest}))\) holds, because claim 2 shows that the minimum is always less than or equal to all the elements in \(\text{selection_sort}(\text{rest})\), and by
IH $\text{selection\_sort}(\text{rest})$ is sorted.

$\therefore$ By the principle of computational induction, the theorem 2.3.2 holds. Q. E. D.
2. INFORMAL PROOFS FOR SORTING
3

Formalization in Isabelle/HOL

3.1 Introduction

This section shows some fragments of the formalized lemmas in Isabelle/HOL. All the lemmas and implementations of the sorting algorithms are available in appendices II, III, and IV. To learn how to formalize in Isabelle/HOL, I extensively used the book Concrete Semantics with Isabelle/HOL, part I [7], the manual The Isabelle/Isar Reference Manual [11], and the article Structured Induction Proofs in Isabelle/Isar [12]. One can use all these references to understand more technical details about the formalizations in the appendices.

3.2 Formalization strategy

In this section, I present the strategy I used to formalize sorting algorithms in Isabelle/HOL. This strategy is essential to avoid pitfalls, such as the belief that Isabelle/HOL proves any lemma directly by writing a few lines of code. From experience, this proof assistant verifies instantly proof steps but not entire lemmas. I suggest the next approach to formalize in Isabelle/HOL:

1. Recursively define the mathematical functions for the algorithms.

2. Write the informal proofs to show particular properties about the algorithms.

3. Implement the mathematical functions in Isabelle/HOL.

4. Formalize proofs in Isabelle/HOL using the Isar language, providing as many proof steps and details as provided in the informal proofs.

5. Use automatic provers such as sledgehammer to verify every proof step.
Indeed, as one gets more experience in Isabelle/HOL and formalization, steps one and two increasingly become redundant. However, for a beginner, it is vital to use the Isar language and present the proof as closely related to the informal proof as possible. In step five, by splitting the lemma into subproblems, the automatic provers are more likely to find a proof, because the search space is much smaller.

### 3.3 Insertion sort

1. **lemma** `sorted3` : "sorted (y#insert x ys) = (y ≤ x ∧ sorted(insert x ys))"
2. **proof** `(induction ys arbitrary: y rule: sorted.induct)`
3. ...
4. `qed`

**Figure 3.1:** Auxiliary lemma for Isabelle/HOL insert_order lemma

1. **lemma** `insert_order` : "sorted(ys) → sorted(insert y ys)"
2. **proof** `(induct ys rule: insert.induct)`
3. ...
4. `show "sorted (y#insert x ys)"
5. `proof`(simp del: sorted.simps add: False sorted3 "local.2.prems")
6. `show "y ≤ x ∧ sorted (insert x ys)"
7. `proof`(rule conjI)
8. `show "y ≤ x" ...
9. `next
10. `have "sorted ys" ...
11. `then show "sorted (insert x ys)" ...
12. `...
13. `qed`

**Figure 3.2:** Proving lemma [I.0.1](insert order) using Isabelle/HOL

Isabelle/HOL provides many predefined lemmas that come along with the sorted function; the simplifier uses these lemmas to rewrite expressions. Some of these lemmas are:

1. **sorted.simps(2):**
   
   \[ \text{sorted } (x#ys) = (\forall y \in \text{set } ys. \ x \leq y) \land \text{sorted } ys \]

2. **sorted2_simps(2):**

   \[ \text{sorted } (x \# y \# zs) = x \leq y \land \text{sorted } (y \# zs) \]
3.4 Merge sort

The lemma `sorted.simps(2)` is too aggressive to prove that the expression `sorted (y#insert x ys)` holds, line 4, figure 3.2, because it associates each element of `insert x ys` to all its successors. To illustrate, by using lemma `sorted.simps(2)` the expression `sorted (y#insert x ys)` rewrites to:

\[ \forall z \in \text{set}(\text{insert} x ys). \ y \leq z \ \land \ \text{sorted}(\text{insert} x ys) \]

For `\forall z \in \text{set}(\text{insert} x ys). \ y \leq z`, not even the automatic theorem provers can find an efficient proof. However, the `sorted2_simps(2)` lemma is less aggressive; it links the insert function directly without the quantifier, but it cannot be applied directly to `sorted (y#insert x ys)` since `sorted2_simps(2)` requires at least two elements.

Unfortunately, Sledgehammer cannot find any adequate proof for proof step in line 4; the automatic provers were taking more than one second to reconstruct the proof. If an automatic prover runs seemingly forever, that is a sign that the proof is too hard for it \[13\]. I solved this issue by adding an auxiliary lemma called `sorted3` in figure 3.1. This auxiliary lemma uses `sorted2_simps(2)` to rewrite `sorted (y#insert x ys)` to:

\[ y \leq x \ \land \ \text{sorted}(\text{insert} x ys) \]

In line 6, figure 3.2, we can see that Isabelle/HOL can indeed rewrite `sorted (y#insert x ys)` to `y \leq x \ \land \ \text{sorted}(\text{insert} x ys)` by using lemma `sorted3`. The automatic provers can find efficient proofs for `y \leq x \ \land \ \text{sorted}(\text{insert} x ys)` that reconstructs under few milliseconds as opposed to more than one second. This section is quite technical, but the bottom line is: the automatic provers are more efficient when using `sorted3` than `sorted2_simps(2).

3.4 Merge sort

Some non-terminating tail-recursive functions are allowed in Isabelle/HOL. However, the vast majority of functions must be total; this means that these recursive functions must halt. Isabelle/HOL has an automatic termination prover, which demands that the arguments of recursive calls on the right-hand side need to be strictly smaller than the arguments on the left-hand side.

The default method for termination proofs is the `lexicographic_order` method. This method search for an adequate lexicographic combination of size measure. Some functions do not have a simple termination argument. In these circumstances, the termination relation has to be set manually \[14\].

Consider the merge function, figure 3.3, which merges two sorted lists. The `lexicographic_order` method fails on this function because it is not clear which argument should
3. FORMALIZATION IN ISABELLE/HOL

```isabelle
function merge :: "nat list ⇒ nat list ⇒ nat list" where
  "merge xs [] = xs" |
  "merge [] ys = ys" |
  "merge (x#xs) (y#ys) = (if x ≤ y then x#merge xs (y#ys) else y#merge (x#xs) ys)"
by pat_completeness auto
termination
proof (relation "measure (λ(xs, ys). length xs + length ys)"")
... assume a1: "x ≤ y"
... show "length xs + length (y#ys) < length (x#xs) + length (y#ys)"
... assume a2: " x ≤ y "
... show "length (x#xs) + length ys < length (x#xs) + length (y#ys)"
... qed
```

Figure 3.3: Proving termination for merge function in Isabelle/HOL

be considered for the standard size ordering. To prove termination manually, we must provide a custom well-founded relation.

First, we need to prove the pattern completeness of the datatype constructors. We show this by issuing the command pat_completeness, line 5. Then we need to proof termination by using the measure function (λ(x,y). length xs + length ys), which states that the standard size is the sum of both arguments, line 7. Finally, we show that in the recursive case, the sum of the lists is strictly smaller than the sum of the original inputs, lines 11 and 15.

3.5 Selection sort

Functions defined with the function keyword come with their induction schema, which follows the recursion schema and derives from the termination arrangement. For example, the selection sort function, appendix IV, proves the tailor-made induction rule:

\[
P[\[] \land \forall x,xs. P\ xs \Rightarrow P(x#xs) \Rightarrow P\ m
\]

This induction rule simplifies inductive proofs. For example, the induction rule in figure 3.3, line 2, produces two subgoals, lines 4 and 10.
3.5 Selection sort

We show some important basic proof patterns for structural induction and calculational reasoning, in figure 3.3. The induction proof automatically creates the subgoals and also the fix-assume steps, which are abbreviated using the case idiom, lines 3 and 6. For example, the case "case (2 x xs)" is an abbreviation for:

```plaintext
fix : x xs
assume hyps: "mset set (selection_sort ?xb) = mset ?xb"
```

We can also reduce the complexity of our proof by entering new assumptions. By using the keyword cases, line 11, we can obtain two additional assumptions, lines 12 and 22. Finally, we show a proof structure for calculational reasoning, lines 13-20, and 23-28, where we produce the proof with the "glue statements" also and finally.

```plaintext
theorem selection_sort_permutation : "mset (selection_sort(xs)) = mset xs"
proof (induct xs rule: selection_sort.induct)
case 1
  then show "mset (selection_sort []) = mset []" by simp
next
case (2 x xs)
  let ?minimum = "Min (set (x # xs))"
  let ?rest = "remove1 ?minimum (x # xs)"
  have III: "mset (selection_sort ?rest) = mset ?rest" using "2. hyps" ...
  then show "mset (selection_sort (x # xs)) = mset (x # xs)"
  proof (cases "?minimum = x")
case True
    have "mset (selection_sort (x # xs)) = mset(?minimum#selection_sort(?rest))" ...
    also have "... = {#?minimum#} + mset(selection_sort(?rest))" ...
    also have "... = {#?minimum#} + mset(?rest)" ...
    also have "... = {#?minimum#} + mset(remove1 x (x # xs))" ...
    also have "... = {#?minimum#} + mset(xs)" ...
    also have "... = mset (x#xs)" ...
    finally show "mset (selection_sort (x # xs)) = mset (x # xs)"
next
case False
  have c1: "mset (selection_sort (x # xs)) = mset(?minimum#selection_sort(?rest))" ...
  also have c2:"... = {#?minimum#} + mset(selection_sort(?rest))" ...
  also have c3:"... = {#?minimum#} + mset(?rest)" ...
  also have c4:"... = {#?minimum#} + mset(x # xs) - {#?minimum#}" ...
  also have c5:"... = mset (x # xs)" by simp
  finally show "mset (selection_sort (x # xs)) = mset (x # xs)"
qed
qed
```

Figure 3.4: Formalizing lemma 2.3.1 (selection_sort permutation) in Isabelle/HOL
Conclusion

This thesis aimed to prove the correctness of some sorting algorithms using the proof assistant Isabelle/HOL. Based on informal proofs, I verified the total correctness of these algorithms by showing that (1) they sort according to the sorting problem, and (2) they eventually terminate. I used the Isar language to present the lemmas in sub-proofs; making the code modular, and maybe easier to maintain.

Surprisingly, I found more challenging verifying selection sort than merge and insertion sort. By assuming that the merge and insertion sort input lists are sorted, one can show that these two algorithms sort correctly. However, to prove that the selection sort output is sorted, I had to verify that the result of its recursive calls does not include new elements.

Even though the automatic theorem provers are excellent for proof search, sometimes they cannot find any proof, because the search space is massive or the current goal is not in first-order logic. Therefore, some level of fundamental mathematics and proof techniques, such as structural or computational induction, is required to break down a problem into subproblems, and because the automatic provers do not attempt to do induction since they are for first-order logic.

\[ \text{insertion\_sort}(x # \text{xs}) = \text{insert}(x, \text{insertion\_sort}(\text{xs})) \]  \hspace{1cm} (I.4)

Figure I.2: insertion\_sort: a recursively defined mathematical function

Lemma I.0.1 (insert order) The insert function yields to sorted list (output) if the element is inserted to a sorted list. Formally:

\[ \forall y, ys (\text{sorted}(ys) \rightarrow \text{sorted}(\text{insert}(y, ys))) \]

PROOF The proof is by structural induction on list \( ys \).

Base case: when \( ys = \text{[]} \), then show that \( \text{sorted}(\text{insert}(y, \text{[]})) \) holds by assuming that \( \text{sorted}(\text{[]}) \) holds.

\[ \text{insert}(y, \text{[]}) = \text{[]} \]  \hspace{1cm} [By definition of insert function]

Hence, \( \text{sorted}(\text{insert}(y, \text{[]})) \) holds because \( \text{sorted}(\text{[]}) \) is sorted.
I. APPENDIX: INSERTION SORT INFORMAL PROOFS

Induction hypothesis:
\[ \forall y, ys (\text{sorted}(ys) \rightarrow \text{sorted}(\text{insert}(y, ys))) \]

Inductive step: assuming that IH holds, then show:
\[ \forall a, y, ys (\text{sorted}(a#ys) \rightarrow \text{sorted}(\text{insert}(y, a#ys))) \]

Fix: a, y, ys
Assume: \text{sorted}(a#ys)

Case 1 \( y < a \).
\[ \text{sorted}(\text{insert}(y, a#ys)) = \text{sorted}(y#a#ys) \]  
[By definition of \text{insert} function and since \( y < a \)]

Hence, \text{sorted}(y#a#ys) holds, because \text{sorted}(a#ys) holds and since \( y < a \).

Case 2 \( y \geq a \). The premise \text{sorted}(a#ys) implies \text{sorted}(ys), because removing the first element of a sorted list leaves the rest of the list sorted. \text{sorted}(\text{insert}(y, ys)) holds by using IH and \text{sorted}(ys). Moreover, \text{insert}(y, a#ys) = \text{sorted}(a#insert(y, ys)) by definition of the \text{insert} and since \( y \geq a \). Hence, \text{sorted}(a#insert(y, ys)) holds, because \text{sorted}(insert(y, ys)) and \text{sorted}(a#ys) holds, and since \( y \geq a \).

\[ \therefore \text{By the principle of structural induction, the lemma } I.0.1 \text{ holds. } \]

Q. E. D.

Theorem I.0.1 (insertion_sort order) The \text{insertion_sort} function yields a sorted list (output). Formally:
\[ \forall ys (\text{sorted}(\text{insertion_sort}(ys))) \]

Proof The proof is by structural induction on list \( ys \).

Base case: when \( ys = [] \), then show that \text{sorted}(\text{insertion_sort}([])) holds by assuming that \text{sorted}([]) holds.
\[ \text{insertion_sort}([]) = [\quad] \]  
[By definition of function \text{insertion_sort}]

Hence, \text{sorted}(\text{insert_sort}([])) holds, because \text{sorted}([]) is sorted.

Induction hypothesis:
\[ \forall ys (\text{sorted}(\text{insert_sort}(ys))) \]
**Inductive step:** assuming that IH holds, then show:

\[ \forall y, ys (\text{sorted}(\text{insert}\_\text{sort}(y\#ys))) \]

Fix: \( y, ys \)

\[
\text{sorted}(\text{insert}\_\text{sort}(y\#ys)) \\
= \text{sorted}(\text{insert}(y, \text{insert}\_\text{sort}(ys))) \quad \text{[By definition of function insertion\_sort]}
\]

Hence, \( \text{sorted}(\text{insert}\_\text{sort}(y\#ys)) \) holds, because (1) \( \text{insert}\_\text{sort}(ys) \) is sorted by using IH, and (2) the lemma I.0.1 states that when the insert function adds any element to a sorted list, then its final output is sorted.

\( \therefore \) By the principle of structural induction, the theorem I.0.1 holds. Q. E. D.

**Lemma I.0.2 (insert permutation)** The insert function output is a permutation of its own input. Formally:

\[ \forall y, ys (\text{mset}(\text{insert}(y, ys)) = \text{mset}(y\#ys)) \]

**Proof** The proof is by structural induction on list \( ys \).

**Base case:** when \( ys = [] \), then show \( \text{mset}(\text{insert}(y, [])) = \text{mset}([y]) \) holds.

\[
\text{mset}(\text{insert}(y, [])) \\
= \text{mset}([y]) \quad \text{[By definition of function insert]}
\]

**Induction hypothesis:**

\[ \forall y, ys (\text{mset}(\text{insert}(y, ys)) = \text{mset}(y\#ys)) \]

**Inductive step:** assuming that IH holds, then show:

\[ \forall a, y, ys (\text{mset}(\text{insert}(y, a\#ys)) = \text{mset}(y\#a\#ys)) \]

Fix: \( y, a, ys \)

**Case 1** \( y < a \).

\[
\text{mset}(\text{insert}(y, a\#ys)) \\
= \text{mset}(y\#a\#ys) \quad \text{[By using insert function definition and since } y < a]\]
I. APPENDIX: INSERTION SORT INFORMAL PROOFS

Case 2 $y \geq a$.

\[ mset(insert(y, a\#ys)) \]
\[ = mset(y\#insert(a, ys)) \quad \text{[By using } \text{insert} \text{ function definition and since } y \geq a] \]
\[ = \{\#y\} + mset(insert(a, ys)) \quad \text{[By mset definition]} \]
\[ = \{\#y\} + mset(a\#ys) \quad \text{[By using IH]} \]
\[ = mset(y\#a\#ys) \quad \text{[By mset definition]} \]

\[ \therefore \text{By the principle of structural induction, the lemma I.0.2 holds.} \quad \text{Q. E. D.} \]

Theorem I.0.2 (insertion_sort permutation) The insertion_sort function output is a permutation of its own input. Formally speaking:

\[ \forall ys (mset(insert_sort(ys)) = mset(ys)) \]

PROOF The proof is by structural induction on list $ys$.

Base case: when $ys = []$, then show $mset(\text{insertion_sort}([])) = mset([])$ holds.

\[ mset(\text{insertion_sort}([])) \]
\[ = mset([]) \quad \text{[By definition of function } \text{insertion_sort} \text{]} \]

Induction hypothesis:

\[ \forall ys (mset(\text{insert_sort}(ys)) = mset(ys))) \]

Inductive step: assuming that IH holds, then show:

\[ \forall y, ys (mset(\text{insert_sort}(y\#ys) = mset(y\#ys)) \]

Fix: $y$, $ys$

\[ mset(\text{insert_sort}(y\#ys)) \]
\[ = mset(\text{insert}(y, (\text{insert_sort}(ys)))) \quad \text{[By } \text{insertion_sort} \text{ function definition]} \]
\[ = mset(y\#(\text{insert_sort}(ys))) \quad \text{[By using lemma I.0.2]} \]
\[ = \{\#y\} + mset(\text{insert_sort}(ys)) \quad \text{[By using mset definition]} \]
\[ = \{\#y\} + mset(y) \quad \text{[By using IH]} \]
\[ = mset(y\#ys) \quad \text{[By using mset definition]} \]

\[ \therefore \text{By the principle of structural induction, the theorem I.0.2 holds.} \quad \text{Q. E. D.} \]
